

Software Testing

Software Testing Part 2 Junit Testing

AY24/25

Week 11

Outline

1. Unit Testing and JUnit
2. Assertion Methods
3. JUnit Test Cycle and Annotation

1. Unit Testing and JUnit

1.1 Review - Unit Testing

- Testing of an individual software unit
 - usually an object class
- Focus on the functions of the unit
 - functionality, correctness, accuracy
- Usually carried out by the developers of the unit

1.2 Review - Automated Framework

- A setup part, where you initialize the system with the test case (e.g., initialize the object under test)
- A call part, where you call the object or method to be tested.
- An assertion part where you compare the result of the call with the expected result. If the assertion evaluates to true, the test has been successful if false, then it has failed.

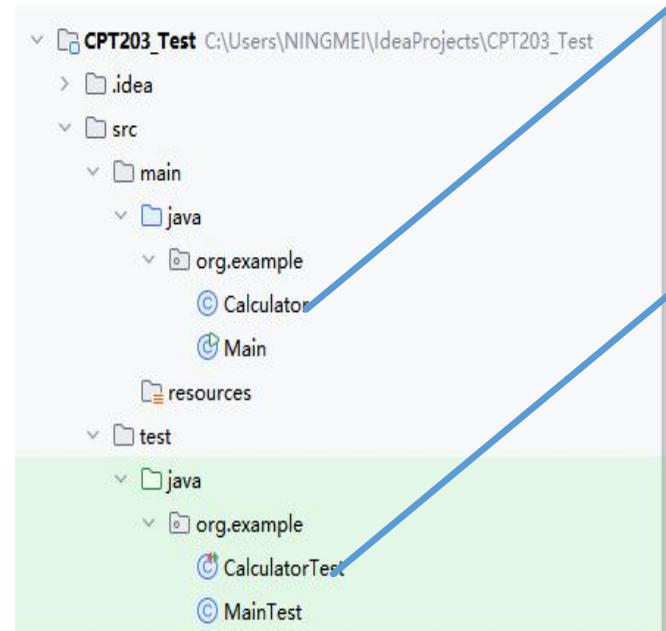

1.3 JUnit

- JUnit is a framework for writing unit tests
 - Designed for the purpose of writing and running tests on Java code
 - A unit test is a test of a single class, where a test case is a single test of a single method
 - Ensures individual test cases are executed in isolation, promoting more accurate results
- Why Junit
 - Enhanced Code Quality
 - Java-based
 - Integrates seamlessly with IDEs like Eclipse and build tools like Maven and Gradle
 - Free

1.3.1 A Junit Test Example

Formally...

Class that is being tested and its test class (where the test is implemented) are separated

Class being tested

```

public class Calculator {    no usages
    public static int add(int x, int y) {
        return x + y;
    }
}

```

A seperate test class

```

package org.example;

import org.junit.jupiter.api.Test;
import static org.junit.jupiter.api.Assertions.*;

class CalculatorTest {
    @Test // Marks the method as a test method.
    public void CalculatorTest() {
        // Setup part - Creating an instance of the class under test,
        // plus the input and expected output
        Calculator calculator = new Calculator(); Instance creation
        int input1 = 5; Define the inputs designed by us
        int input2 = 3;
        int Expected = 8; Define the EXPECTED output

        // Call Part
        // Calling the method to be tested with some inputs.
        int ActualResult = calculator.add(input1, input2); Actual output we get

        // Assertion Part
        // Asserting that the method returned the expected value.
        assertEquals(Expected, ActualResult, message: "Message we want to show");
    }
}

```

Annotating marking a test will be implemented

method (expected (1st var), actual (2nd var), msg (optional))

1.3.1 A Junit Test Example

Sometime...

```
import org.junit.jupiter.api.Test;
import static org.junit.jupiter.api.Assertions.*;

public class Calculator{
    public static int add(int x,int y) {
        return x + y;
    }

    // The Test class itself
    // Often named after the class it's testing
    // (e.g., CalculatorTest for Calculator class)

    @Test // Marks the method as a test method.
    public void CalculatorTest() {
        // Setup part - Creating an instance of the class under test,
        // plus the input and expected output
        Calculator calculator = new Calculator();
        int input1 =5;
        int input2 = 3;
        int Expected = 8;

        // Call Part
        // Calling the method to be tested with some inputs.
        int ActualResult = calculator.add(input1, input2);

        // Assertion Part
        // Asserting that the method returned the expected value.
        assertEquals(Expected, ActualResult, message: "Message we want to show");
    }
}
```

Class being tested and its test class can be in the same class

```
@Test // Marks the method as a test method.
public void CalculatorTest() {
    // Setup part - Creating an instance of the class under test,
    // plus the input and expected output
    Calculator calculator = new Calculator();

    // Call Part
    // Calling the method to be tested with some inputs.
    int ActualResult = calculator.add( x: 5, y: 3); Input directly defined in the call part

    // Assertion Part
    // Asserting that the method returned the expected value.
    assertEquals(expected: 8, ActualResult, message: "Message we want to show");
}
```

Expected output directly defined in the assertion part

1.3.2 Junit Test Verdicts

A verdict is the result of executing a single test case.

Pass

- The test case execution was completed
- The function being tested performed as expected

Fail

- The test case execution was completed
- The function being tested did not perform as expected

Error

- The test case execution was not completed, due to
 - an unexpected event, exceptions, or
 - improper set up of the test case, etc.

1.3.2 Junit Test Verdicts (cont.)

- If the tests run correctly, a test method does nothing but shows the results in Green

The screenshot shows a mobile application interface. On the left, there is some Java code:

```
int input1 = 5;
int input2 = 3;
int Expected = 8;
```

An orange arrow points from this code to the right side of the screen. On the right, the application displays the results of a Java command:

```
C:\Users\NINGMEI\.jdks\openjdk-22\bin\java.exe ...
```

Below this, a green box highlights the text "Tests passed: 1 of 1 test - 12 ms" with a checkmark icon. At the bottom of the screen, the text "Process finished with exit code 0" is displayed.

1.3.2 Junit Test Verdicts (cont.)

- If a test fails

```
int input1 = 5;  
int input2 = 3;  
int Expected = 9;
```

The screenshot shows a Java JUnit test run. The code being tested is:

```
30     assertEquals(Expected, ActualResult, message: "Message we want to show");  
31 }
```

The test fails, indicated by a red box around the status bar message "Tests failed: 1 of 1 test - 16 ms". The failure details are shown in a red box:

Result in Red

org.opentest4j.AssertionFailedError: Message we want to show ==>
Expected :9
Actual :8

Details

[Click to see difference](#)

A red box highlights the error message "Message we want to show ==>". A red arrow points from this message to the text "Error Msg we typed, changable". Another red arrow points from the same message to the text "Logs".

The stack trace is shown in a red box:

```
<4 internal lines>  
at Calculator.CalculatorTest(Calculator.java:30) <29 internal lines>  
at java.base/java.util.ArrayList.forEach(ArrayList.java:1597) <9 internal lines>  
at java.base/java.util.ArrayList.forEach(ArrayList.java:1597) <27 internal lines>
```

Below the stack trace, the logs indicate disconnection and the process exit code:

Disconnected from the target VM, address: '127.0.0.1:50394', transport: 'socket'
Process finished with exit code -1

Where

Logs

1.3.2 Junit Test Verdicts (cont.)

- If an error happens

```
Calculator calculator = new Calculatorsss();  
int input1 =5;  
int input2 = 3;  
int Expected = 8;
```

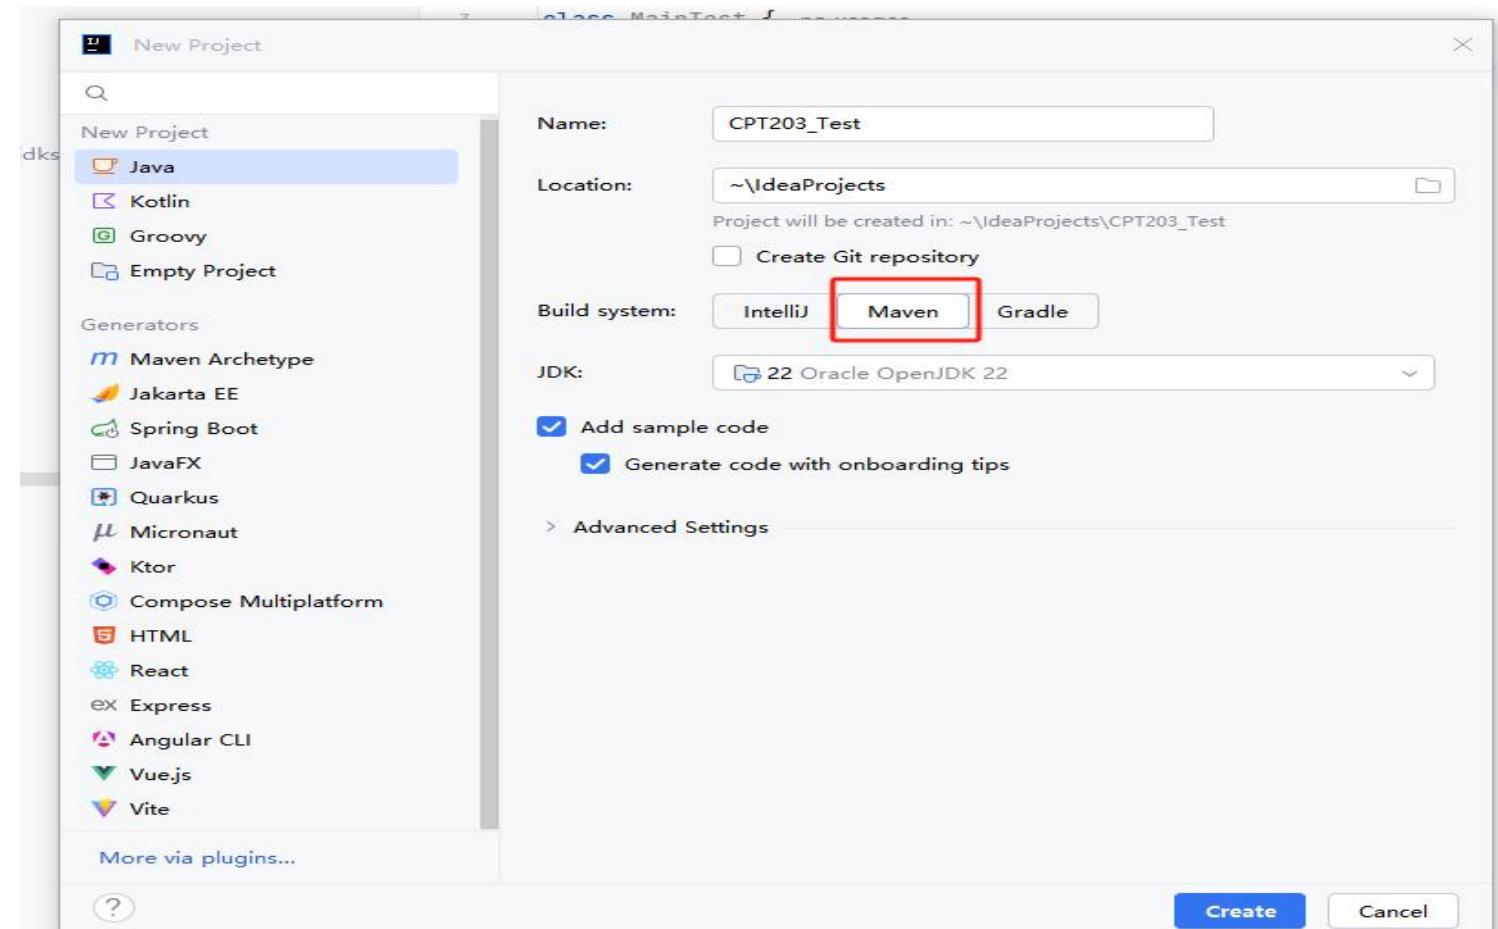

C:\Users\NINGMEI\IdeaProjects\123123\src\Calculator.java:19:37
java: 找不到符号
 符号: 类 Calculatorsss
 位置: 类 Calculator

1.4 JUnit Best Practices

- Tests need *failure atomically* (ability to know exactly what failed).
 - Each test should have a clear, long, descriptive name.
 - Assertions should always have clear messages to know what failed.
 - Write many small tests, not one big test.
 - Each test should have roughly just 1 assertion at its end.
- Test for expected errors / exceptions.
- Choose a descriptive assert method, not always `assertTrue`.
- Choose representative test cases from equivalent input classes.
- Avoid complex logic in test methods if possible.

1.5 Configure JUnit in IntelliJ

- Create a New Project (e.g., Maven)

1.5 Run JUnit in IntelliJ (cont.)

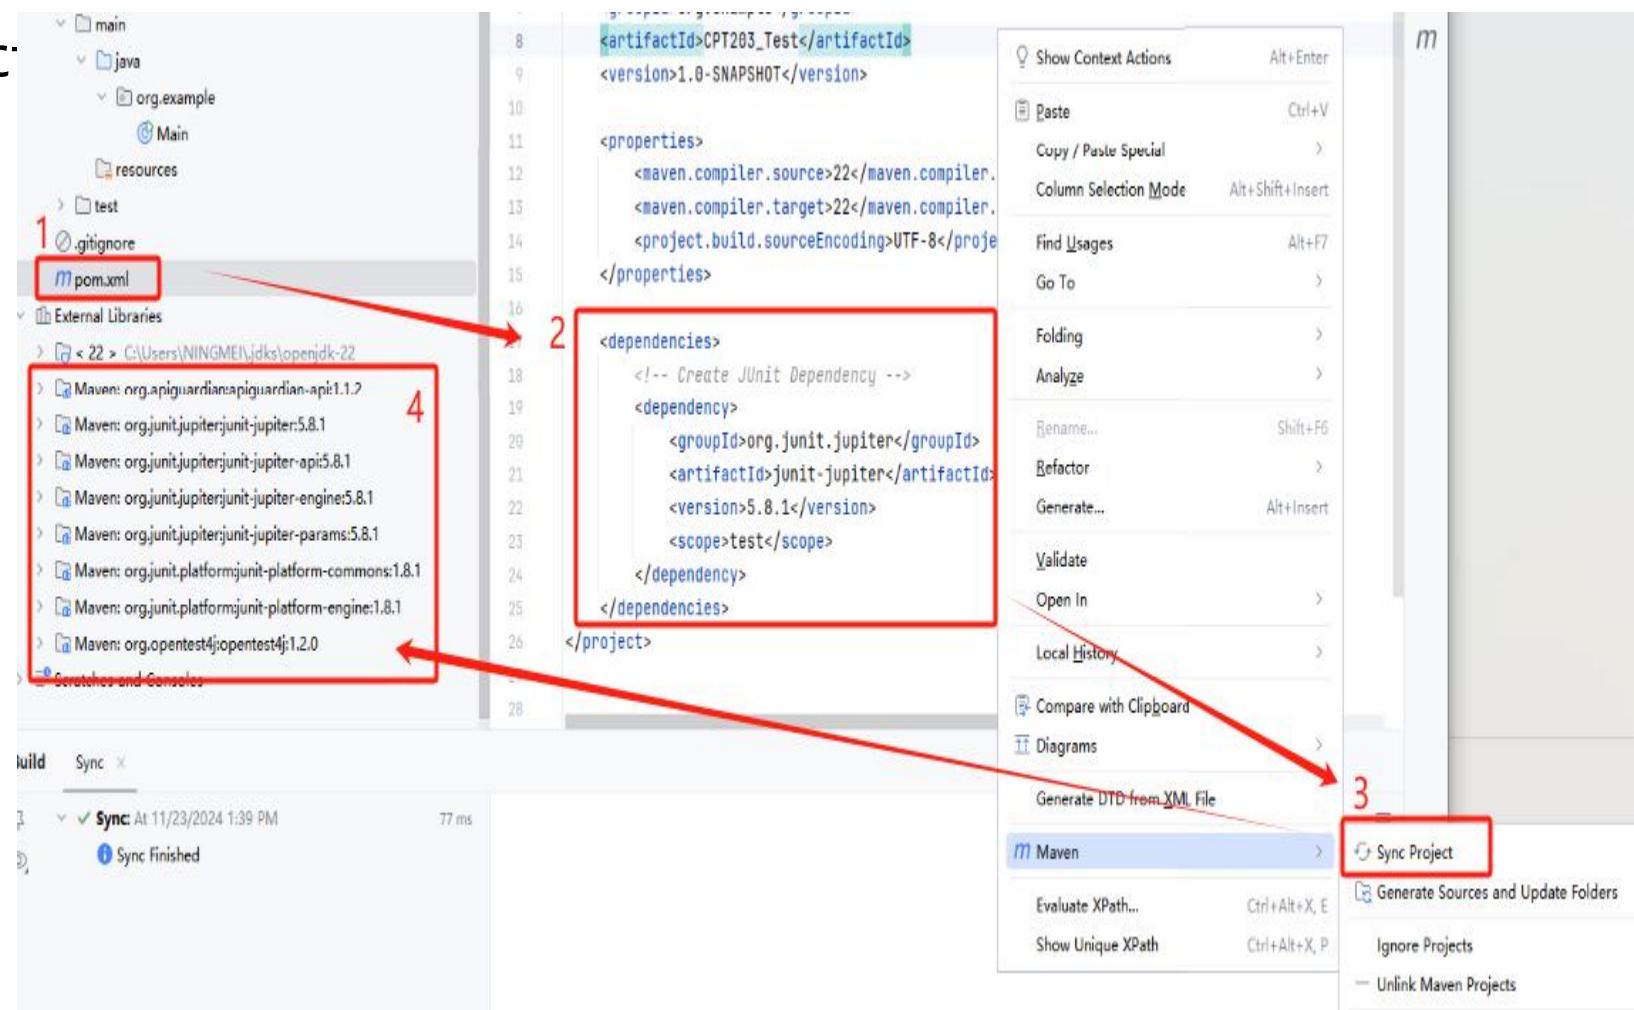

1. Click “pom.xml” in the project root directory

2. Add dependency

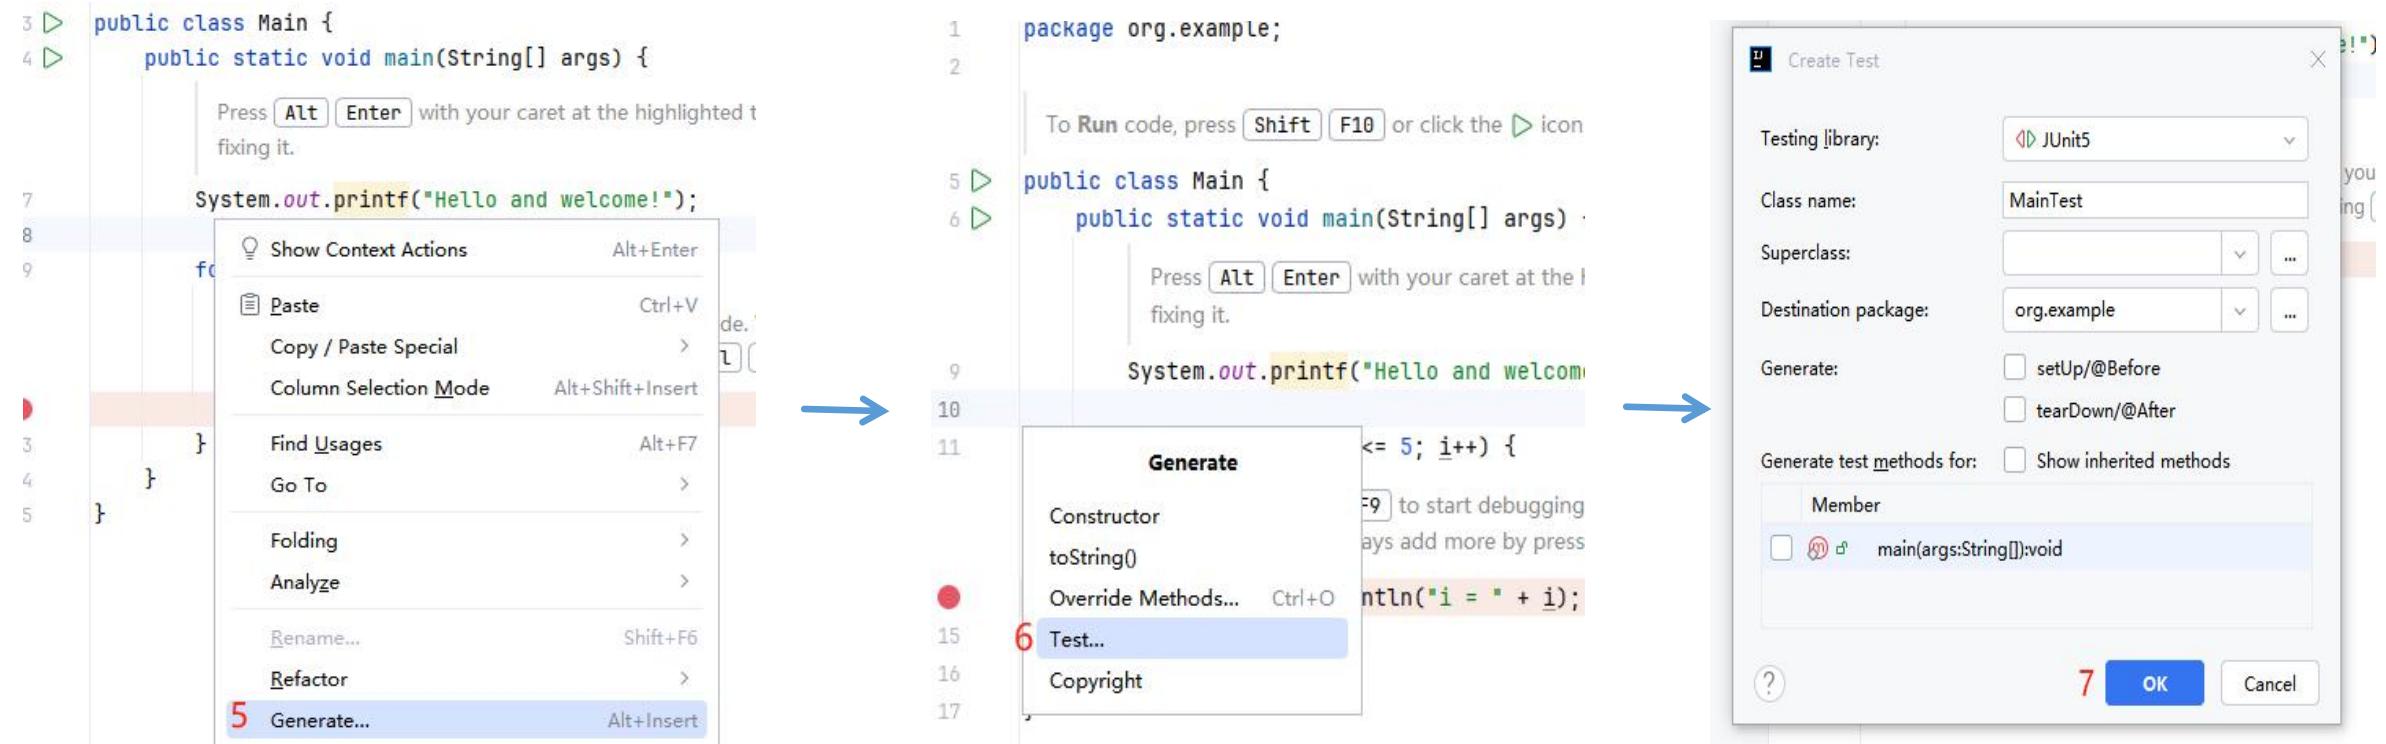

```
<dependencies>
    <dependency>
        <groupId>org.junit.jupiter</groupId>
        <artifactId>junit-jupiter</artifactId>
        <version>5.8.1</version>
        <scope>test</scope>
    </dependency>
</dependencies>
```

3. Right click -> Maven -> Sync Project

4. You see the dependencies

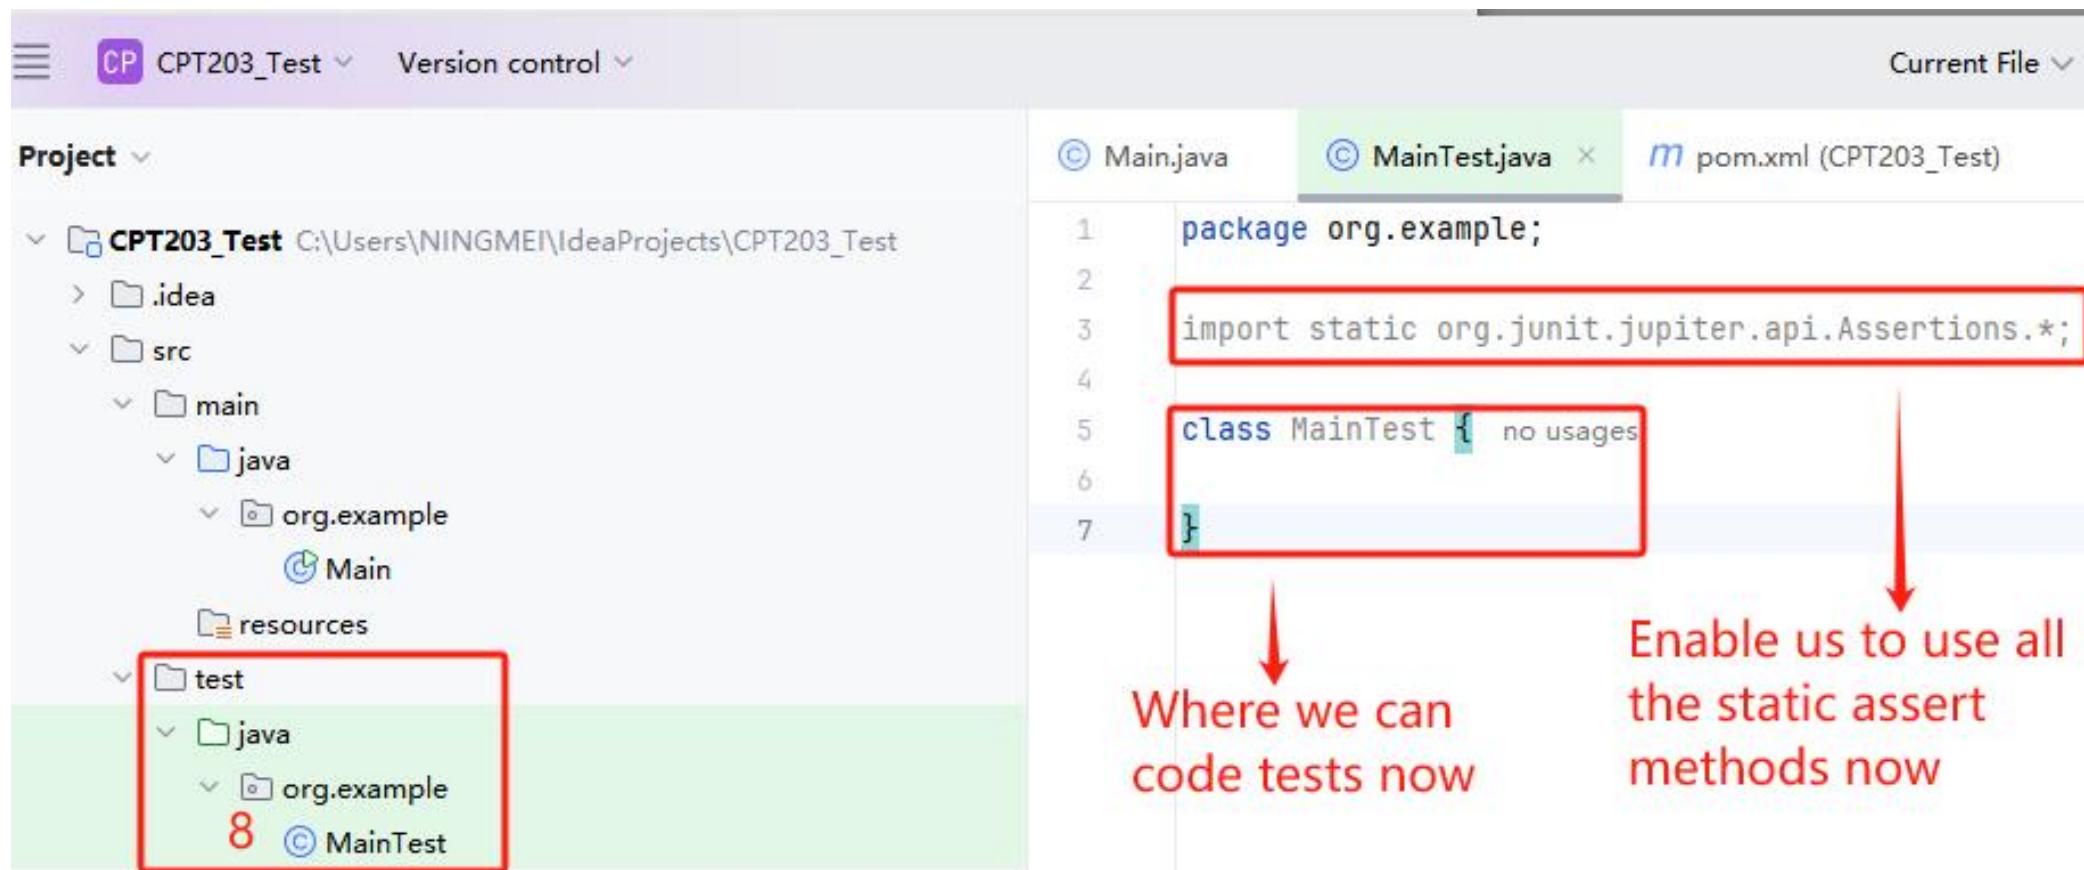

1.5 Run JUnit in IntelliJ (cont.)

5. To verify we can use Junit now, reight click in the Main class, and select **Generate**
6. Select **Test**
7. Select **OK**

1.5 Run JUnit in IntelliJ (cont.)

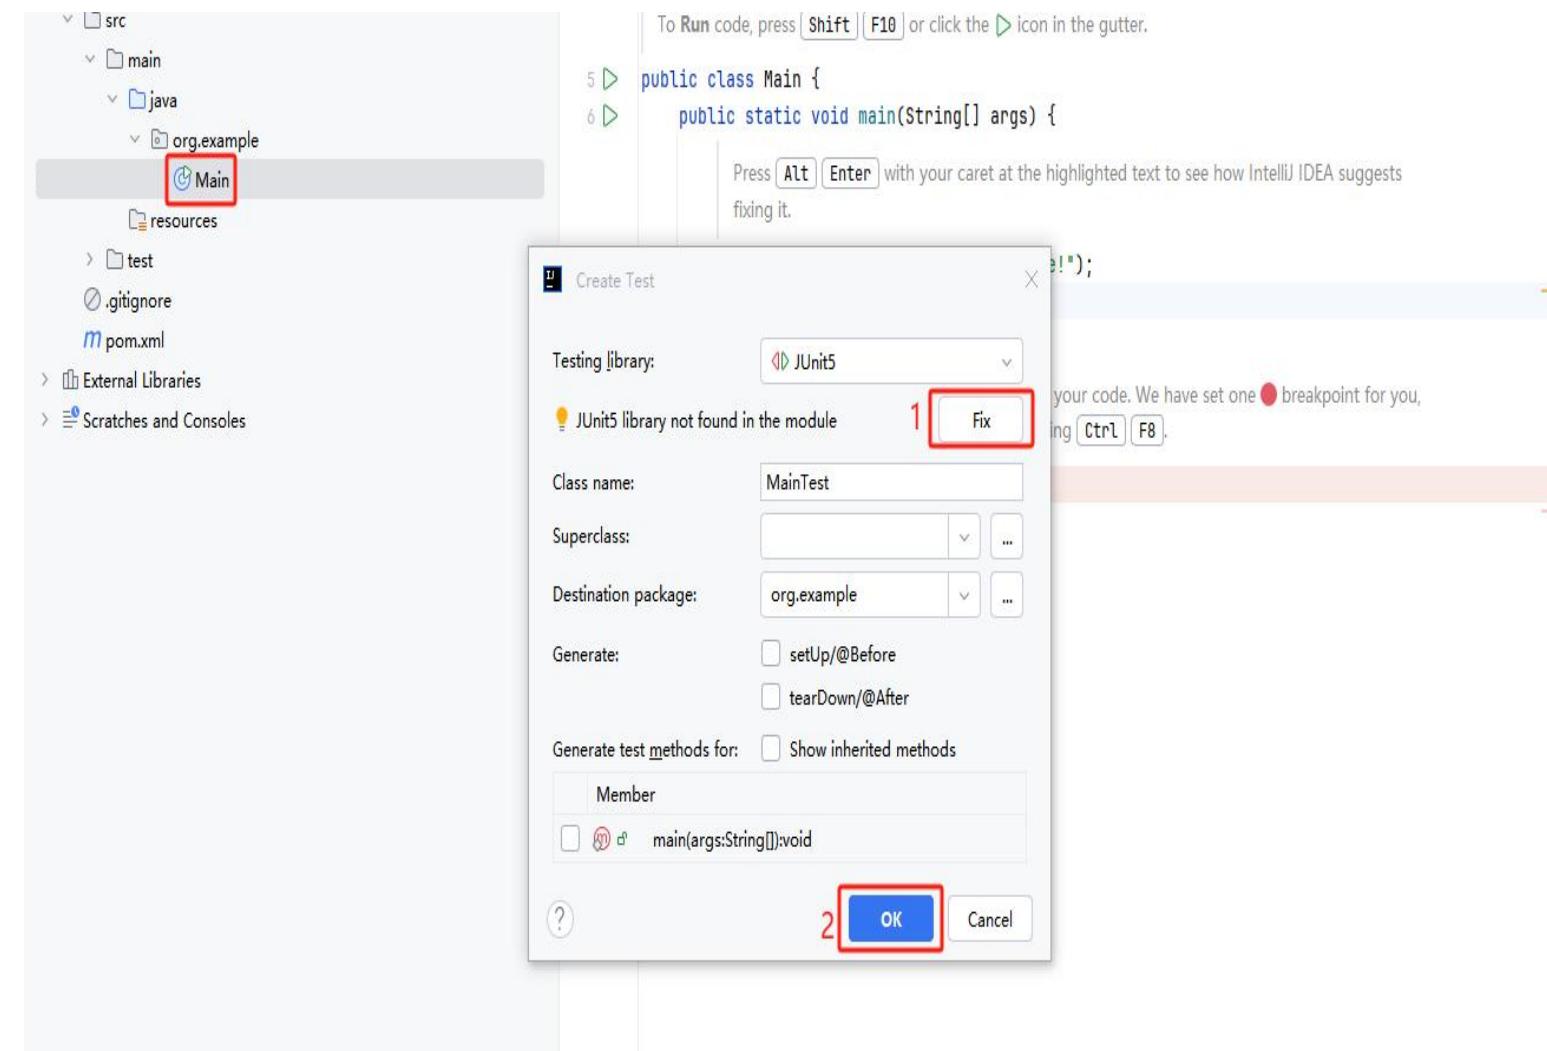

8. A test class named MainTest is generated under test file (becasue we were generating test in the Main class)

1.5 Run JUnit in IntelliJ (cont.)

Or a much quicker way

- Create a Maven Project
- Right click in Main class -> Generate -> Test
- At the window poped up, click Fix and then OK
- Done :)

2. Assertion Methods

2.1 AssertTrue/AssertFlase

- Assert a Boolean condition is true or false

`assertTrue(condition)`

`assertFalse(condition)`

- Optionally, include a failure message

`assertTrue(condition, message)`

`assertFalse(condition, message)`

```
public class NumberChecker { 2 usages
    public boolean isPositive(int number) { 1 usage
        return number > 0;
    }
}
```

```
package org.example;

import org.junit.jupiter.api.Test;
import static org.junit.jupiter.api.Assertions.*;

class NumberCheckerTest {

    @Test
    public void testIsPositive() {
        NumberChecker checker = new NumberChecker();
        boolean isPositive = checker.isPositive( number: 5);
        assertTrue(isPositive);
        assertFalse(isPositive, message: "This failure message is optional");
    }
}
```

报错，期望是 False,
报错显示内容

2.2 AssertSame/AssertNotSame

- Assert two object references are identical

`assertSame(expected, actual)`

- True if: expected == actual

`assertNotSame(expected, actual)`

- True if: expected != actual

- With a failure message

`assertSame(expected, actual, (optional) message)`

`assertNotSame(expected, actual, (optional) message)`

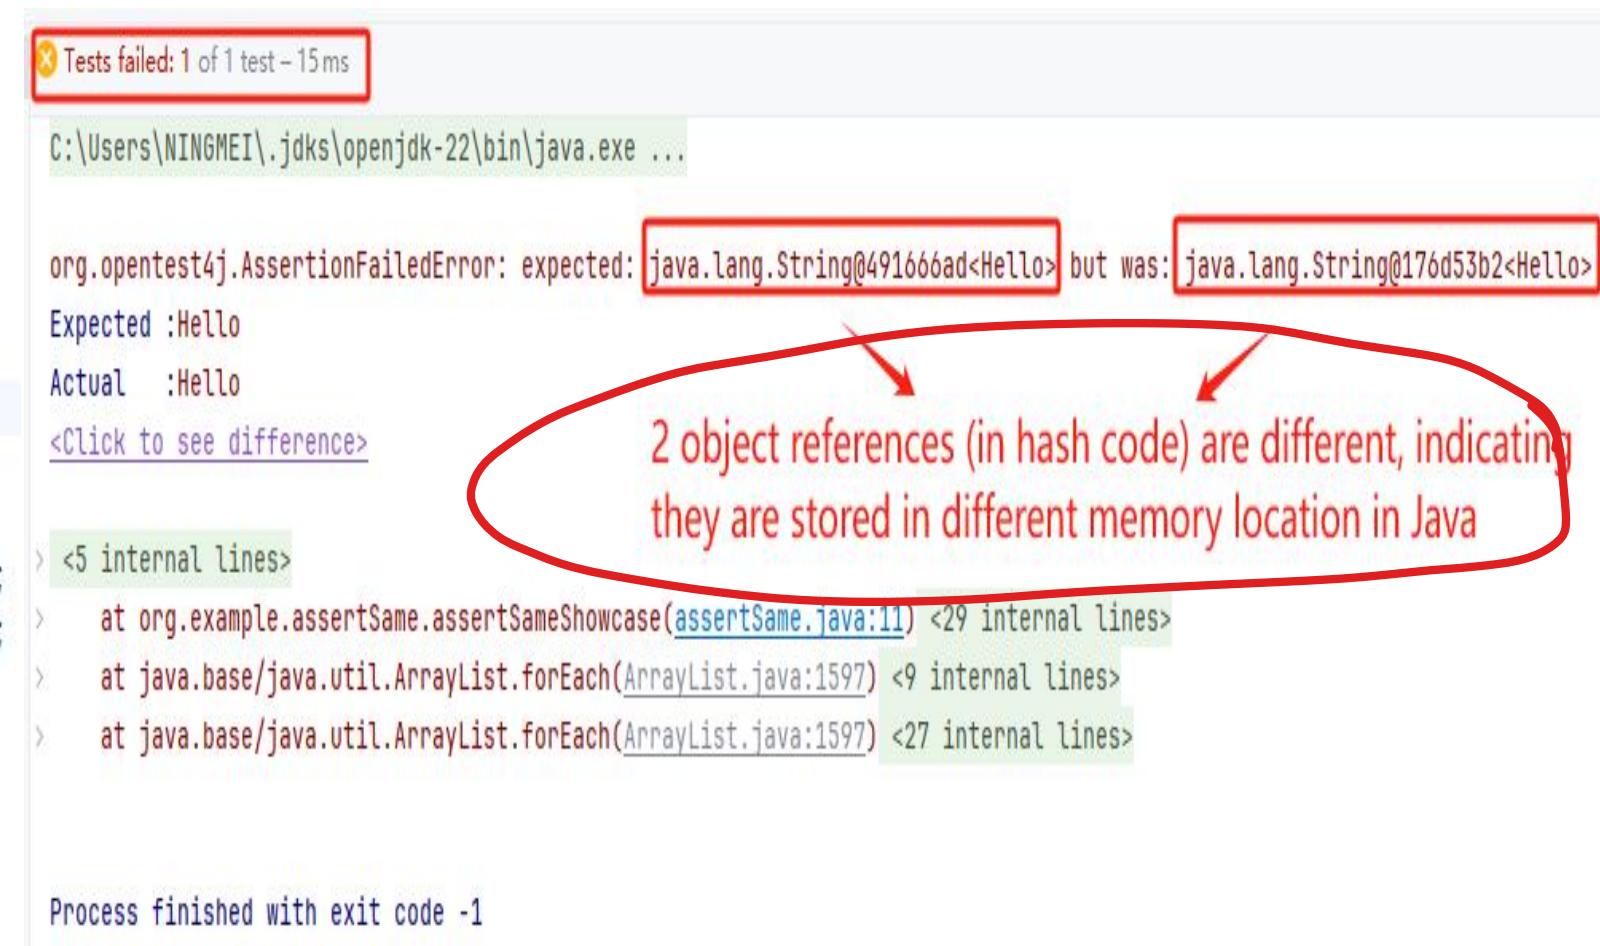

- Note: Compare if two objects are exactly the same → False
one, NOT the value

at assertSame -

2.2 AssertSame/AssertNotSame (cont.)

```
package org.example;

import org.junit.jupiter.api.Assertions;
import org.junit.jupiter.api.Test;
public class assertSame {
    @Test
    public void assertSameShowcase() {
        String s1 = new String( original: "Hello");
        String s2 = new String( original: "Hello");
        Assertions.assertSame(s1, s2);
    }
}
```

2.3 assertEquals/AssertNotEquals

- Assert two objects are equal to each regarding value/content
- It doesn't matter if expected and actual are the same object or different object; as long as their content is equal, the test will pass.
- Not only for int type, but also for other values (e.g., string, float, ...)

相比 assertSame 好处不一致。

package org.example;

“类”

```
public class StringCase { 2 usages
    public String combining(String one, String two) { 1 usage
        return one + two;
    }
}
```

```
package org.example;
import org.junit.jupiter.api.Test;
import static org.junit.jupiter.api.Assertions.assertEquals;

public class assertEquals {
    @Test
    public void testCombining() {
        StringCase SC = new StringCase();

        String expected = "HelloWorld";
        String actual = SC.combining( one: "Hello", two: "World");

        assertEquals(expected, actual);
    }
}
```

2.4 AssertArrayEquals

- Assert two arrays are equal:

`assertArrayEquals(expected, actual, (optional) message)`

- arrays must have same length
- Recursively check for each valid index *i*,

```
public class Array { 1 usage

    public static int[] generateArray() { 1 usage
        return new int[] {1,2,3};
    }
}
```

```
package org.example;

import org.junit.jupiter.api.Test;

import static org.junit.jupiter.api.Assertions.*;

class ArrayTest {
    @Test
    public void testArray() {
        int[] expectedArray = new int[] {3, 2, 1};
        int[] actualArray = Array.generateArray();
        assertArrayEquals(expectedArray, actualArray);
    }
}
```

} 会失败

2.5 AssertThrows

- Used to test that a specific type of exception is thrown during the execution of a block of code
- assertThrows(expectedExceptionClass, executable)
 - expectedExceptionClass is the type of exception you expect
 - executable is a *lambda expression* or a method reference that executes the code under test
- Particularly useful for negative test cases where you want to ensure that your code fails under certain conditions

2.5 AssertThrows (cont.)

package org.example;

```
public class AssertThrowsCalcCase {
    public double divide(int numerator, int denominator) {
        if (denominator == 0) {
            throw new ArithmeticException("Division by zero is not allowed");
        }
        return (double) numerator / denominator;
    }
}
```

```
class AssertThrowsCalCaseTest {
    @Test
    public void testDivisionByZeroThrowsException() {
        // Create an instance of the AssertThrowsCalCase class.
        // This class contains the 'divide' method we want to test.
        AssertThrowsCalCase calculator = new AssertThrowsCalCase();

        // Use assertThrows to test that an ArithmeticException is thrown.
        // assertThrows takes two main parameters:
        // 1. The class of the exception we expect to be thrown.
        // 2. A lambda expression that executes the code we're testing.
        assertThrows(
            //The expected exception type.
            //Here, we expect an ArithmeticException.
            ArithmeticException.class,
            // This is the Lambda expression.
            // It is used to execute the 'divide' method of the calculator object.
            // The 'divide' method is called with arguments 10 and 0.
            () -> calculator.divide( numerator: 10, denominator: 0));
    }
}
```

Annotations and annotations:

- Red circle 1: `@Test`
- Red circles 2: `AssertThrowsCalCase calculator = new AssertThrowsCalCase();`
- Red circle 3: `ArithmeticException.class`
- Red box 4: `() -> calculator.divide(numerator: 10, denominator: 0));`
- Red arrow 5: Points to the text "Lambda #3" with a handwritten note.

Annotations:

- Parameter List
- operator
- Body: method being tested with the case (10 and 0)

2.5 AssertThrows (cont.)

Why use Lambda (Correct Approach):

- `assertThrows(ArithmeticException.class, () -> calculator.divide(10, 0));`
- This approach delays the execution of divide until assertThrows can catch the exception.

Otherwise (Problematic):

- `assertThrows(ArithmeticException.class, calculator.divide(10, 0))`
- In this case, divide is executed immediately, and if it throws an exception, it happens before assertThrows can catch it, leading to a test error.

3. JUnit Test Cycle and Annotation

3.1 Life Cycle

- Normally, a test class contains multiple test methods. JUnit manages the execution of each test method in form of a lifecycle.
- The complete lifecycle of a test case can be seen in three phases with the help of annotations.

3.2 Life Cycle Phases

- 1. Setup:** This phase puts the test infrastructure in place. JUnit provides class level setup (`@BeforeAll`) and method level setup (`@BeforeEach`). Generally, heavy objects like database connections are created in class level setup while lightweight objects like test objects are reset in the method level setup.
- 2. Test Execution:** In this phase, the test execution and assertion happen. The execution result will signify a success or failure.
- 3. Cleanup:** This phase is used to cleanup the test infrastructure setup in the first phase. Just like setup, teardown also happen at class level (`@AfterAll`) and method level (`@AfterEach`).

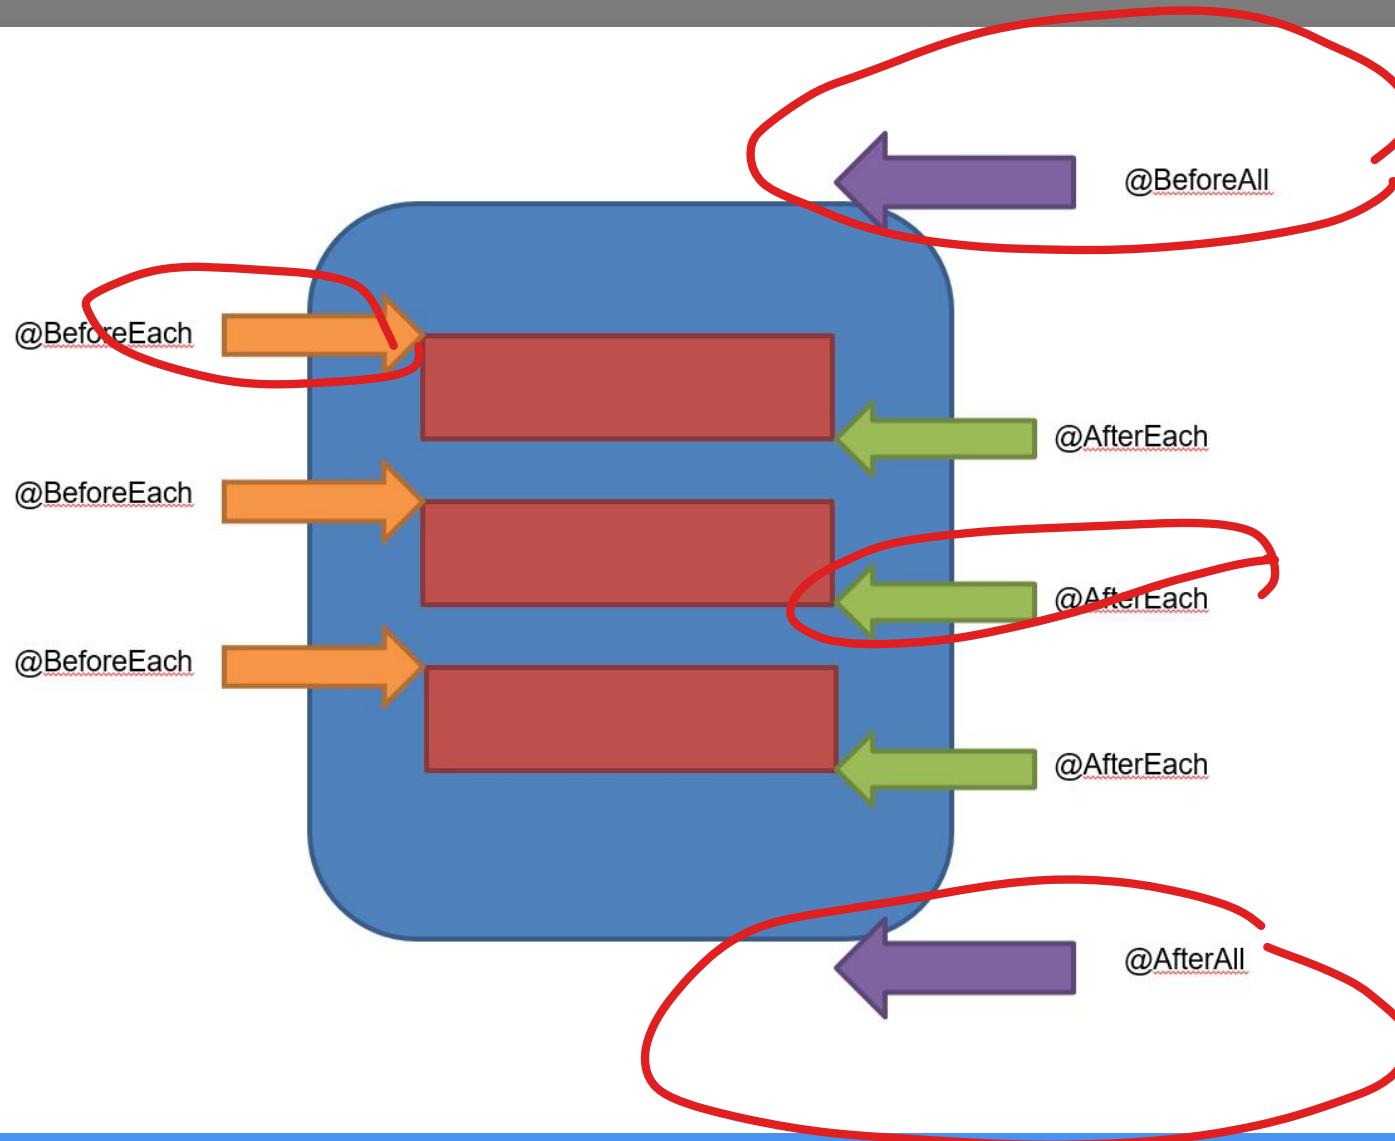

3.2 Life Cycle Phases (cont.)

In the test life cycle, we will primarily need to have some annotated methods to setup and cleanup the test environment or test data on which the tests run.

In JUnit, by default, for each test method – a new instance of test is created.

1. `@BeforeAll` and `@AfterAll` annotations – clear by their name – should be called only once in the entire tests execution cycle. So they must be declared **static**.
2. `@BeforeEach` and `@AfterEach` are invoked for each instance of test so they should not be static.

3.2 Life Cycle Phases (cont.)

3.2 Life Cycle Phases (cont.)

```
import static org.junit.jupiter.api.Assertions.assertEquals;  
  
public class JunitLifecycle {  
  
    // Class level setup - runs once before all tests  
    @BeforeAll e.g., link to the whole database  
    static void setupClass() {  
        // Code to set up database connections or other heavy resources  
    }  
  
    // Method level setup - runs before each test  
    @BeforeEach e.g., select a specific dataset for the test below  
    void setupTest() {  
        // Code to initialize or reset test objects  
    }  
  
    // Actual test case  
    @Test Test implementation  
    void testExample() {  
        // Test execution and assertions  
        assertEquals( expected: 2, actual: 1 + 1);  
    }  
  
    // Method level cleanup - runs after each test  
    @AfterEach e.g., clean up the specific dataset for next round of test  
    void tearDownTest() {  
        // Code to reset or clean up after each test  
    }  
  
    // Class level cleanup - runs once after all tests  
    @AfterAll e.g., Disconnect the whole database and end test  
    static void tearDownClass() {  
        // Code to clean up database connections or other heavy resources  
    }  
}
```

3.3 Junit 5 Annotations

Annotation	Description
<code>@BeforeEach</code>	The annotated method will be run before each test method in the test class.
<code>@AfterEach</code>	The annotated method will be run after each test method in the test class.
<code>@BeforeAll</code>	The annotated method will be run before all test methods in the test class. This method must be static.
<code>@AfterAll</code>	The annotated method will be run after all test methods in the test class. This method must be static.
<code>@Test</code>	It is used to mark a method as a junit test.
<code>@DisplayName</code>	Used to provide any custom display name for a test class or test method
<code>@Disable</code>	It is used to disable or ignore a test class or test method from the test suite.
<code>@Nested</code>	Used to create nested test classes
<code>@Tag</code>	Mark test methods or test classes with tags for test discovering and filtering
<code>@TestFactory</code>	Mark a method is a test factory for dynamic tests.

3.3.1 @DisplayName

- **@DisplayName // to display meaningful name appear in the test report**

```
@DisplayName("I need a name")
//@RepeatedTest(3)
@Test
void test1()
{
    System.out.println("=====TEST ONE EXECUTED=====");
    assertEquals( expected: 4 , Calculator.add( x: 2, y: 2));
}
```

The screenshot shows a Java test report interface. At the top, there are various icons for navigating through the test results. Below the icons, a summary message reads "Tests passed: 1 of 1 test - 10ms". The main area displays the test results in a table-like format. The first row shows a green checkmark next to the test name "testAnnotations" and its duration "10ms". The second row shows a green checkmark next to the test name "I need a name" and its duration "10ms". To the right of the table, the command used to run the test is shown: "C:\Users\NINGMEI\.jdks\openjdk-22\bin\java.exe ...". Below the command, several lifecycle methods are listed: "@BeforeAll executed", "@BeforeEach executed", "=====TEST ONE EXECUTED=====", "@AfterEach executed", and "@AfterAll executed". At the bottom of the report, the message "Process finished with exit code 0" is displayed.

Test	Status	Duration
testAnnotations	✓	10ms
I need a name	✓	10ms

3.3.2 @Timeout

- Useful for simple performance test
 - Network communication
 - Complex computation
- The **@Timeout** annotation
 - Time unit defaults to seconds (@Timeout (1)) but is configurable

```
@DisplayName("I need a name")
//@RepeatedTest(3)
@Timeout(value = 1, unit= TimeUnit.MILLISECONDS)
@Test
void test1()
{
    System.out.println("=====TEST ONE EXECUTED=====");
    assertEquals( expected: 4 , Calculator.add( x: 2, y: 2));
}
```

The screenshot shows a terminal window with the following output:

```
Tests failed: 1 of 1 test - 16 ms
C:\Users\NINGMEI\.jdks\openjdk-22\bin\java.exe ...
@BeforeAll executed
@BeforeEach executed
=====TEST ONE EXECUTED=====
@AfterEach executed

java.util.concurrent.TimeoutException: test1() timed out after 1 millisecond
> <26 internal lines>
>     at java.base/java.util.ArrayList.forEach(ArrayList.java:1597) <9 internal lines>
>     at java.base/java.util.ArrayList.forEach(ArrayList.java:1597) <27 internal lines>
```

A red box highlights the error message "Tests failed: 1 of 1 test - 16 ms". A red arrow points from this message to the text "16ms > 1ms, so failed" which is written in red at the bottom right of the terminal window. Another red arrow points from the "16 ms" part of the error message to the "16ms > 1ms" text.

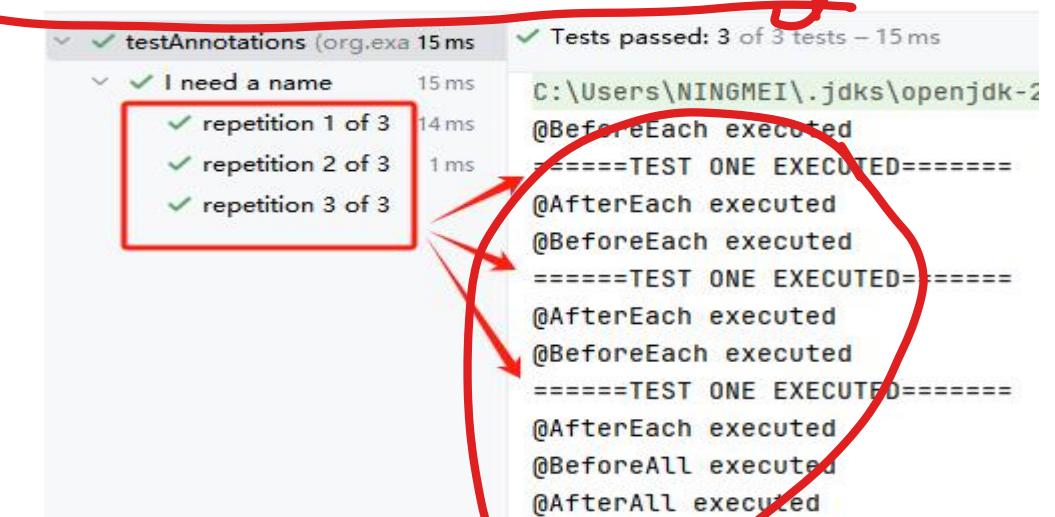

3.3.3 @RepeatedTest

- **@RepeatedTest** is used to mark a test method that should repeat a specified number of times with a configurable display name.
- In the given example, the test method uses **@RepeatedTest(3)** annotation. It means that the test will be executed 3 times.
- **@Test** would **NOT** be needed if we are using **@RepeatedTest**

```

    @DisplayName("I need a name")
    @RepeatedTest(3)
    // @Test
    void test1()
    {
        System.out.println("=====TEST ONE EXECUTED=====");
        assertEquals( expected: 4 , Calculator.add( x: 2, y: 2));
    }

```

3.3.3 @RepeatedTest (cont.)

- **@RepeatedTest** is used to mark a test method that should repeat a specified number of times with a configurable display name.
- In the given example, the test method uses **@RepeatedTest(3)** annotation. It means that the test will be executed 3 times.
- **@Test** would **NOT** be needed if we are using **@RepeatedTest**

```
@DisplayName("I need a name")
@RepeatedTest(3)
//@Test
void test1()
{
    System.out.println("=====TEST ONE EXECUTED=====");
    assertEquals( expected: 4 , Calculator.add( x: 2, y: 2));
}
```

Otherwise, output:

...[A Warning Message (not an error)]... +
This is typically the result of annotating a
method with multiple competing annotations
such as **@Test**, **@RepeatedTest**,
@ParameterizedTest, **@TestFactory**, etc
